

SMART MANAGER

Live-Site Architecture and Workflow Report

Senior architecture inspection of <https://menejajanja.vercel.app> · 23 August 2026 · read-only public session

Executive assessment. The live site presents Smart Manager as a Tanzania-oriented enterprise ERP command center. The public landing page and /app workspace gateway were verified. The anonymous session exposed the secure sign-in surface, so authenticated dashboard operations, business mutations, backend procedures, and database persistence were not directly tested.

Evidence level	Meaning
Verified	Directly visible in the public live pages or captured browser runtime.
Verified client evidence	Found in the publicly served production bundle; establishes frontend vocabulary, not backend completion.
Inferred / supplied context	Architecture detail drawn from the inherited project context and labelled explicitly where not observable anonymously.
Not tested	Requires authenticated access, controlled fixture data, provider callbacks, or mutation execution.

Senior architecture conclusion. The correct evolution path is a shared ERP shell with bounded domain workspaces and centralized controls for authentication, tenancy, permissions, persistence, auditability, financial posting, reconciliation, reporting, notifications, and scheduled execution. Every unverified server-side claim is labelled in the following pages.

Live evidence captured during inspection

These screenshots document the observable public states. No credentials were entered and no form was submitted.

Public landing page. Verified product positioning, connected capability messaging, Tanzania branding, and route toward the workspace.

Workspace entry. Verified secure sign-in surface, visible navigation vocabulary, module-focus selector, and provider options.

Evidence caveat: the public landing page describes product capabilities, while the /app route stopped at authentication in the anonymous session. Marketing copy and client bundle vocabulary must not be treated as proof that every workflow is live, persistent, or accessible to every role.

1. Live public system context

Smart Manager live-site architecture · evidence-bounded view

Smart Manager — Live Public System Context

Senior architect interpretation. The live URL has two observed states: a public product surface and a secure workspace entry route. The browser verified the Vercel-hosted HTTPS page, the Smart Manager identity, the route into /app, and the visible authentication-provider boundary. The architecture treats identity and hosting as external dependencies that should be isolated behind adapters.

2. Live frontend composition

Smart Manager live-site architecture · evidence-bounded view

Smart Manager — Live Frontend Composition

Senior architect interpretation. The production client is Vite-based and lazy-loads the BusinessSphereDashboard feature. Public source metadata references App.tsx, Home.tsx, NotFound.tsx, BusinessSphereDashboard.jsx, and shared workspaces. This supports a shared React shell with lazy-loaded feature boundaries; bundle growth and cross-feature coupling remain important engineering risks.

3. Live workspace module map

Smart Manager live-site architecture · evidence-bounded view

Senior architect interpretation. The visible workspace navigation establishes Dashboard, Point of Sale, Sales, Inventory, Finance, CRM, Human Resources, Reports, and AI Assistant. The public lazy bundle also contains vocabulary for financial inclusion, vertical industries, supply chain, fleet, workflow, documents, collaboration, and settings. These are client-side capability signals, not proof of authenticated persistence.

4. Verified anonymous authentication workflow

Smart Manager live-site architecture · evidence-bounded view

Smart Manager — Verified Anonymous Workspace Workflow

Senior architect interpretation. The anonymous path is verified through the sign-in gateway only. The page exposes work email/password, passkey, Google, Microsoft, and Apple options. The successful-authentication branch is explicitly not verified because no credentials were submitted. A production implementation should resolve tenant and role server-side after authentication.

5. Evidence-bounded runtime and data architecture

Smart Manager live-site architecture · evidence-bounded view

Smart Manager — Runtime and Data Architecture (Evidence-Bounded)

Senior architect interpretation. Browser routing is verified from the live build. The application server, Supabase business data, RLS, tenant isolation, and object storage are marked inferred from the supplied project context rather than anonymous live evidence. This distinction prevents a frontend bundle from being mistaken for proof of backend workflow health.

6. Senior business workflow model

Smart Manager live-site architecture · evidence-bounded view

Smart Manager — Senior Business Workflow Model

Senior architect interpretation. The product flow is modeled as authenticated entry, command-center selection, domain workflow, shared control points, and action-ready outcome. Commercial, finance, people, financial inclusion, and vertical-service flows should converge on validation, role checks, audit, reconciliation, and reporting rather than duplicate those controls.

7. Live deployment observation

Smart Manager live-site architecture · evidence-bounded view

Smart Manager — Live Deployment Observation

Senior architect interpretation. The public URL verified delivery of a Vercel-served HTML shell, Vite assets, and a lazy dashboard chunk. It did not verify repository ownership, deployment freshness, server/API health, migrations, authenticated access, or provider settlement. Release acceptance should include ready deployment status and authenticated smoke tests.
